AB Neural stem cells/progenitors that give rise to neurons and glia have been identified in different regions of the brain, including the embryonic retina and ciliary epithelium of the adult eye. Here, we first demonstrate the characterization of neural stem/progenitors in postnatal iris pigment epithelial (IPE) cells. Pure isolated IPE cells could form spheres that contained cells expressing retinal progenitor markers in non-adherent culture.

Case # 10/559, 783.
STN (BIOSIS, MEDLINE)
AD 4/23/07

The spheres grew by cell proliferation, as indicated by bromodeoxyuridine incorporation. When attached to laminin, the spheres forming IPE derived cells were able to exhibit neural phenotypes, including retinal-specific neurons. When co-cultured with embryonic retinal cells, or grafted into embryonic retina in vivo, the IPE cells could also display the phenotypes of photoreceptor neurons and Muller glia. Our results suggest that the IPE derived cells have retinal stem/progenitor properties and neurogenic potential without gene transfer, thereby providing a novel potential source for both basic stem cell biology and therapeutic applications for retinal diseases.

ABSTRACT:

A process for producing retinal neurocytes, comprising conducting differentiation induction of iris pigmented epithelial cells into retinal neurocytes. The first process comprises co-culturing iris pigmented epithelial cells derived from a mammal and embryo retinal stem cells derived from a bird. The second process comprises isolating iris pigmented epithelial cells of a bird, a mammal, etc. and subjecting the iris pigmented epithelial cells to stationary culture. In these processes, retinal neurocytes can be produced with the use of iris pigmented epithelial cells collected from a patient per se, so that realization of highly effective regenerative medicine is promising.

ABSTRACT:

A process for producing tissue cells derived from iris pigment epithelial cells of an animal, by which problems, such as concern about immunological rejection caused by cell transplantation, ethical issues and unbalance between the demand and supply on transplant cell sources, can be solved; and tissue cells produced by the process. In this process for producing tissue cells, first, iris pigment epithelial cells isolated from an animal eyeball are selectively cultured according to a floated coagulated mass culturing technique to thereby obtain pluripotent stem cells. Thereafter, these pluripotent stem cells are cultured with the use of, for example, serum to thereby effect production of various tissue cells.

ABSTRACT:

[Machine Translation of Descriptors]. The nervous trunk cell which is obtained problem and ethical problem of the immunity refusal due to the cell transplantation in central nervous type playing back, by the production method, and its method of the nervous trunk cell of iris pigment epithelium cell origin of the mammal which can solve problem such as demand for transplantation cell source and imbalance of supply is offered. The nervous trunk cell is produced by discretionary culturing the iris pigment epithelium cell which is isolated from the eyeball of the mammal with floating cohesion soul culture method.
